

# Bambu

## POST MAINTENANCE

cabiokid

in cooperation with

Insects and other potential residents should be checked on regularly.

Vegetation will attract insects, rodents and fungi on the bamboo

**TERMITES** eat their way through the inside of bamboo. Contact with soil or any hole should be avoided and regular checks should coincide with immediate action.

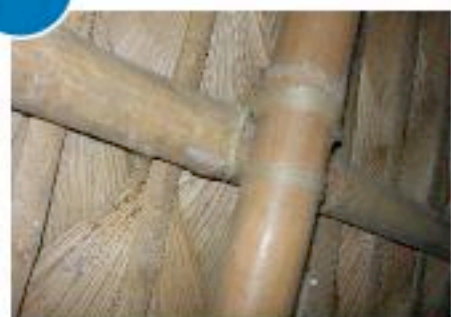

**RODENTS** gnaw on bamboo and perforate its nodes. This may cause structural weakening of a building.

Screening, regular cleaning and checking on dust, cracks or other abnormalities are the best strategies in maintaining bamboo or other natural materials. With proper care, its lifespan can be extended to 20 years.

**CLIMATE** should also be considered as a limiting factor. Water is a major cause for fungi to develop. Good **roofing**, **paint** or **footing** can protect the bamboo from rot.

Bamboo is kept beautiful and strong with oil and water based chemicals. They will turn the "grass" in a durable and sustainable product.
